

# 1 Supporting Information

2  
 3 **S1 Figure:** Relationship between wind stress and currents. The upper-left insert presents the  
 4 rotary spectrum of the wind stress. Here, the red line indicates clockwise rotations (CW) and the  
 5 black line counter-clockwise (CCW) rotations. The bar indicates the 95% confidence interval.  
 6 The coherence and phase spectra between  $\tau_y$  and the along-fjord component in the upper 10 m are  
 7 presented in contour plots. In the coherence, black lines indicate coherences over 80% (thin) and  
 8 99% (wide) confidence levels. In the phase spectra, only phases with coherences over 80%  
 9 confidence levels were plotted (the thin black line obtained from the coherence spectra). To  
 10 emphasize the changes in phase, we included the  $0^\circ$  contour (wide black line) in the phase  
 11 spectra. The mean profile of the along-fjord currents and the mean  $\tau_y$  were included in the right  
 12 inserts. Dashed vertical lines denote the three-day, one-day, inertial ( $f$ ), and 12-hour periods.

1  
2 **S2 Table:** Locations of the ADCP and sealevel moorings and the meteorological station. Here  
3 presents details of the time series measured on the Reloncavi fjord. You must notice that the error  
4 (\*) on the ADCP, results from the measurement configuration whereas the accuracy and  
5 resolution came from factory.  
6
