10 Abstract

11 Equimolar tris (2-amino-2-hydroxymethyl-propane-1,3-diol) buffer in artificial seawater is a well characterized
12 and commonly used standard for oceanographic pH measurements. We evaluated the stability of tris pH when stored
13 in flexible, gas impermeable bags across a variety of experimental conditions, including bag type, tris batch, and
14 storage in air vs. seawater over 300 days. Bench-top spectrophotometric pH analysis revealed that the pH of tris stored
15 in bags drifted at a rate of $-0.0058 \pm 0.0008 \text{ yr}^{-1}$ (mean slope \pm 95% confidence interval of slope). Analyses of total
16 dissolved inorganic carbon confirmed that a combination of CO₂ infiltration and/or microbial respiration led to the
17 observed decrease in pH. Eliminating bagged tris pH drift remains a goal, yet the pH drift rate of 0.006 yr^{-1} is lower
18 than many processes of interest and demonstrates the value of bagged tris to sensor calibration and validation of
19 autonomous in situ pH measurements.

20 1. Introduction

21 Ocean pH is a key measurement used for tracking biogeochemical processes such as photosynthesis,
22 respiration, and calcification (Takeshita et al., 2016); and represents perhaps the most recognized variable associated
23 with ocean acidification (OA), the decrease in ocean pH due to the uptake of anthropogenic carbon dioxide (Doney et
24 al., 2009). OA progresses with a global average pH decline of 0.002 per year in the surface open ocean (Bates et al.,
25 2014), and the accumulated and projected near-term effects of OA have been shown to have deleterious effects on
26 many calcifying organisms (Cooley and Doney, 2009). Beyond the narrow scope of calcifiers, organismal response is
27 complex, exhibiting varied responses across processes such as reproduction, growth rate, and sensory perception.
28 Organismal responses are further complicated by their impact on ecosystem level dynamics, such as altering
29 competition and predator-prey relationships (Doney et al., 2020). Furthermore, pH effects are often exacerbated by
30 concomitant stressors, such as decreased dissolved oxygen or increased temperature. Ultimately, OA will affect
31 humans through impacts on fisheries, aquaculture, and shoreline protection (Branch et al., 2013; Doney et al., 2020).

32 The quality of pH measurement required to observe various phenomena is often broken into “climate” and
33 “weather” levels of uncertainty (Newton et al., 2014), or 0.02 and 0.003, respectively. Discrete sampling has been
34 shown to be capable of meeting the climate level of uncertainty when best practices are followed, yet many labs do
35 not consistently meet this standard (Bockmon and Dickson, 2015). Furthermore, while discrete, bench-top
36 methodologies can be the most accurate, the ocean’s vast size limits the oceanographic community’s ability to make
37 ship-based discrete pH measurements, to roughly once per decade throughout most of the ocean (Sloyan et al., 2019).
38 The sparsity of ship-board measurements hinders our ability to assess sub-decadal processes, such as seasonal cycles
39 or bloom events, over much of the ocean (Karl, 2010), and highlights the need for autonomous, high-frequency pH
40 measurements. Technological advancements have led to more routine autonomous pH measurements over the past
41 decade, providing opportunities to fill some gaps in time and space in discrete sampling programs (e.g. Byrne, 2014;
42 Martz et al., 2015; Lai et al., 2018; Wang et al., 2019; Tilbrook et al., 2019). Globally, pH sensors now operate on
43 hundreds of autonomous platforms including moorings and profiling floats, delivering unique datasets in the form of
44 Eulerian and depth resolved Lagrangian time series (Johnson et al., 2017; Bushinsky et al., 2019; Sutton et al., 2019).

45 While sensors increase data coverage, many sensor-based pH measurements, particularly on moored systems, continue
46 to fall short of both climate and weather levels of uncertainty, as highlighted in the intercomparison tests carried out
47 by the Alliance for Coastal Technologies (ACT, 2012) and by the Wendy Schmidt Ocean Health XPRIZE (Okazaki
48 et al., 2017).

49 Independent validation is typically required for autonomous sensors to meet both weather and climate levels
50 of uncertainty. For example, autonomous underway $p\text{CO}_2$ systems (Pierrot et al., 2009), moorings (Bushinsky et al.,
51 2019), and autonomous surface vehicles (Chavez et al., 2017; Sabine et al., 2020) are able to provide climate quality
52 observations with an uncertainty of $\pm 2 \mu\text{atm}$ because traceable standard gases are frequently measured in situ. For pH
53 measurements on profiling floats (Johnson et al., 2016), sensor performance is validated by comparing to a deep
54 reference pH field that is calculated using empirical algorithms (Williams et al., 2016; Bittig et al., 2018; Carter et al.,
55 2018). This approach has demonstrated the ability to obtain high quality pH measurements from a network of profiling
56 floats (Johnson et al., 2017) but requires measurements in the deep, comparatively stable ocean. It is atypical for other
57 pH sensors, including coastal moored sensors, to have an automated or remote validation. Therefore, on such
58 deployments, validation has largely relied on discrete samples taken alongside the sensor (Bresnahan et al., 2014;
59 McLaughlin et al., 2017; Takeshita et al., 2018), which presents unique challenges; primarily that spatiotemporal
60 discrepancy can lead to errors of > 0.1 , especially in highly dynamic systems (Bresnahan et al., 2014).

61 Similar to the method in use by $p\text{CO}_2$ systems, one approach to validate in situ pH sensors is by measuring a
62 reference material or pH standard, one or more times during a sensor deployment. The most commonly used standard
63 for oceanographic pH measurement is equimolar tris (2-amino-2-hydroxymethyl-propane-1,3-diol) buffer in artificial
64 seawater, hereafter referred to as tris (DeValls and Dickson, 1998). The pH of tris has been characterized over a range
65 of temperature, salinity, and pressure (DeValls and Dickson, 1998; Rodriguez et al., 2015; Takeshita et al., 2017;
66 Müller et al., 2018), allowing for accurate calculation of tris pH across a wide range of marine conditions. Furthermore,
67 when stored in borosilicate bottles and under ideal conditions, these buffers have been shown to be stable to better
68 than 0.0005 over a year (Dickson, 1993; Nemzer and Dickson, 2005), making tris a good candidate for in situ
69 validation of long term deployments of autonomous pH sensors. To be utilized for in situ applications, the reference
70 solution must be stored in flexible bags (as in, Hales et al., 2005; Seidel et al., 2008; Sayles and Eck, 2009; Spaulding
71 et al., 2014; Wang et al., 2015; Lai et al., 2018). Recently, in situ sensor validation using bagged tris was demonstrated
72 by Lai et al. (2018) during a 150 day deployment of an autonomous pH sensor, where the tris standard was measured
73 in situ every 5 days. However, the stability of tris when stored in bags has not been quantified systematically using
74 spectrophotometric bench-top pH measurement techniques recommended as best practices (Dickson et al., 2007).

75 In this work we quantified the stability of tris stored in bags for 300 days. Tris from four separately prepared
76 batches was stored in two bag types either in a lab or submerged in seawater. In addition, one batch was stored in
77 borosilicate bottles in the lab as a control. Spectrophotometric pH measurements were made approximately every two
78 months on each bag of tris. Throughout the experiment, Certified Reference Materials (CRMs) for CO_2 (Dickson,
79 2001) were used to assess the stability of the spectrophotometric pH system.

80 2. Methods

81 Two bag types were tested for storing tris (Figure 1). Bag type 1 is based on a design used in the “Burke-o-
82 Lator” system (Hales et al., 2005; Bandstra et al., 2006), made from PAKDRY 7500 barrier film (IMPAK P75C0919).
83 The barrier film is made of layers of polyester and nylon with a sealant layer of metallocene polyethylene. Two 23 x
84 48 cm (9” x 19”) sheets were heat sealed on three sides, forming a pocket, and a 1.9 cm ($\frac{3}{4}$ ”) diameter hole was cut
85 into one of the pocket walls for the bulkhead fitting and bulkhead nut (McMaster-Carr 8674T55). The bulkhead was
86 sealed into the wall with a silicone gasket (McMaster-Carr 9010K13), washer (McMaster-Carr 95649A256), and
87 coated with silicone sealant (McMaster-Carr 74955A53). A “push-to-connect” ball valve fitting (McMaster-Carr
88 4379K41), was attached to the bulkhead. The modified pocket was rinsed, dried, and heat sealed along the final edge
89 to create a ~4 L bag. Bags were left to dry for at least 24 hours before filling. Bag type 2 was a 3 L Cali-5-Bond bag
90 purchased from Calibrated Instruments and used without modification. It is a multi-layer bag made of plastic,
91 aluminium foil (to prevent liquid and gas permeation), a layer of inert HDPE (to form a non-reactive inner wall) and,
92 a polycarbonate Stopcock Luer valve.

Figure 1: A picture of bag type 1 and 2 used to store tris in this study.

93 In this experiment, four batches of tris were prepared following the procedure in DeIvalls and Dickson
94 (1998), using off-the-shelf reagents with no additional standardization or purification (e.g. recrystallization of salts).
95 The focus of this paper is stability of bagged tris over time and does not prioritize obtaining highly accurate equimolar
96 tris (as would be necessary for characterization of thermodynamic constants, for example). The calculated pH of tris
97 in this study was 8.2652 at 20°C, based on quantity of reagents used. This is 0.0135 higher than the pH of equimolar
98 tris, 8.2517 at 20°C (DeIvalls and Dickson, 1998). The pH discrepancy was due to a unit error in the measurement of
99 HCl (our preparation used mol/L rather than the prescribed mol/kg-sol). Reagents used include: tris (2-amino-2-
100 hydroxymethyl-propane-1,3-diol), Fisher Scientific, PN: T395-1, lot 170360; NaCl, Fisher Scientific, PN: S641-212,

101 lot 127252; Na₂SO₄, Fisher Scientific, PN: S421-1, lot 134837; KCl, Fisher Scientific, PN: P217-500, lot 174416;
102 MgCl₂, Teknova, PN: M0304, lot M030427E1401; CaCl₂, Amresco, PN: E506-500mL, lot 0982C089; HCl, Fisher
103 PN: SA48-1, lot 175004 (batch 1, 2 and 3), lot 188768 (batch 4).

104 Three stability tests were initiated at different times over the course of 18 months. The initiation of a given
105 test is defined as the date of preparation of the tris used in that test. A summary of the differences between these tests
106 is shown in Table 1 and described here. Each bag has a unique identifier in the format of “Batch #, Bag #, Lab or
107 Tank.” Test 1: Tris batches 1 and 2 in bag types 1 and 2 were used. Each bag was rinsed before filling; 3 times with
108 deionized water (DI), 5 times with ultrapure water (> 18 MΩ resistivity) and 3 times with 200 mL of tris. Tris bags
109 were stored on a lab bench or in a 5,000 L test tank filled with ozone-sterilized, filtered seawater. Test 2: Tris from
110 batch 3 was used and followed the same procedure as test 1. Bag type 2 experienced delamination of exterior layers
111 when stored in seawater and was not used in further testing.

112 Test 3: Tris from batch 4 and only bag type 1 were used. Each bag was rinsed before filling; 3 times with DI,
113 5 times with ultrapure water, and at least 6 times with 200 mL of tris. Multiple bags of type 1 containing the same
114 batch of tris were stored on a lab bench; these bags are differentiated with letters A to D. Bag 1A was rinsed with 200
115 mL of tris 6 times before filling. Additionally, tris from batch 4 was stored in borosilicate bottles following the
116 procedure in Nemzer and Dickson (2005). Bags and bottles were stored on a lab bench (no tank storage). In addition
117 to pH measurements, dissolved inorganic carbon (C_T) was measured on both bagged and bottled tris to see if changes
118 in pH were due to increased CO₂. C_T samples were measured using a custom-built system based on an infrared analyser
119 (LI-COR 7000) similar to systems used by O'Sullivan and Millero (1998) and Friederich et al. (2002). The precision
120 of the C_T measurements was $\pm 1.4 \mu\text{mol/kg}$ (pooled standard deviation, $n_{\text{samples}}=15$, $n_{\text{measurements}}=44$).

121 **Table 1: Tris preparation and storage.**

| | Bag Type | Tris Batch | Date Made | Storage Location | Rinse Procedure | C_T Measured |
|--------|------------|------------|------------------|------------------|--|----------------|
| Test 1 | 1 & 2 | 1 & 2 | 13 Dec 2017 | Lab & Tank | 3x DI, 5x ultrapure, 3x tris | No |
| Test 2 | 1 & 2 | 3 | 13 April 2018 | Lab & Tank | 3x DI, 5x ultrapure, 3x tris | No |
| Test 3 | 1 & bottle | 4 | 26 February 2019 | Lab | 3x DI, 5x ultrapure, $\geq 6x$ tris | Yes |

122

123 Tris pH was measured every 55 ± 20 days (mean \pm standard deviation of measurement interval) throughout
124 the experiment. The pH of tris was measured in triplicate at each time point with spectrophotometry using m-cresol
125 purple as the indicator dye (mCP, Aldrich, lot MKBH6858V) using the system described in Carter et al. (2013).
126 Absorbance measurements were made in a 10-cm jacketed cell, and the temperature was measured directly adjacent
127 to the cell outflow using a NIST-traceable thermometer (± 0.1 °C, QTI DTU6028P-001-SC). Blank and sample were
128 held for 3 minutes in the jacketed flow cell prior to absorbance measurements. On average, temperature was stable to
129 within a 0.02 °C range over the course of the day; the mean temperature throughout the experiment was 20.09 ± 0.23
130 °C (1 σ), although temperature was 0.6 °C higher than the average on one measurement day. Spectrophotometric pH

131 measurements are reported at 20 °C by adjusting the measured pH value at the measured cell temperature T_C
132 (pH_{spec,T_C}) to 20 °C ($pH_{spec,20^\circ C}$) using the known temperature dependence of tris (pH_{tris}) as follows:

$$pH_{spec,20^\circ C} = pH_{spec,T_C} - (pH_{tris,T_C} - pH_{tris,20^\circ C}) \quad (1)$$

133 pH_{tris,T_C} and $pH_{tris,20^\circ C}$ were calculated using Eq. (18) in DelValls and Dickson (1998). Throughout the experiment,
134 CRMs (procured from A. Dickson, Scripps Institution of Oceanography) for seawater C_T and total alkalinity were
135 measured regularly to verify instrument performance (Dickson, 2001). A time-series of CRM measurements over the
136 duration of the work described here showed no systematic drift. (Fig. A1 in Appendix A).

137 To account for pH-dependent errors from impurities in unpurified mCP, a pH-dependent correction factor
138 was determined based on the protocol outlined in Liu et al. (2011). Briefly, pH of seawater was measured subsequently
139 using impure dye (pH_{impure}) and purified dye (pH_{pure}) over a range of pH between 7.4 to 8.2 at approximately 0.2
140 intervals. Triplicate measurements were made at each pH. A second order pH-dependent error was observed as
141 previously described, following the equation ($R^2 = 0.975$, $RMSE = 0.000434$):

$$pH_{pure} = pH_{impure} - 0.0047777 \times pH_{impure}^2 + 0.0668875 \times pH_{impure} - 0.2359740 \quad (2)$$

142 All pH_{spec} reported in this study has this correction applied.

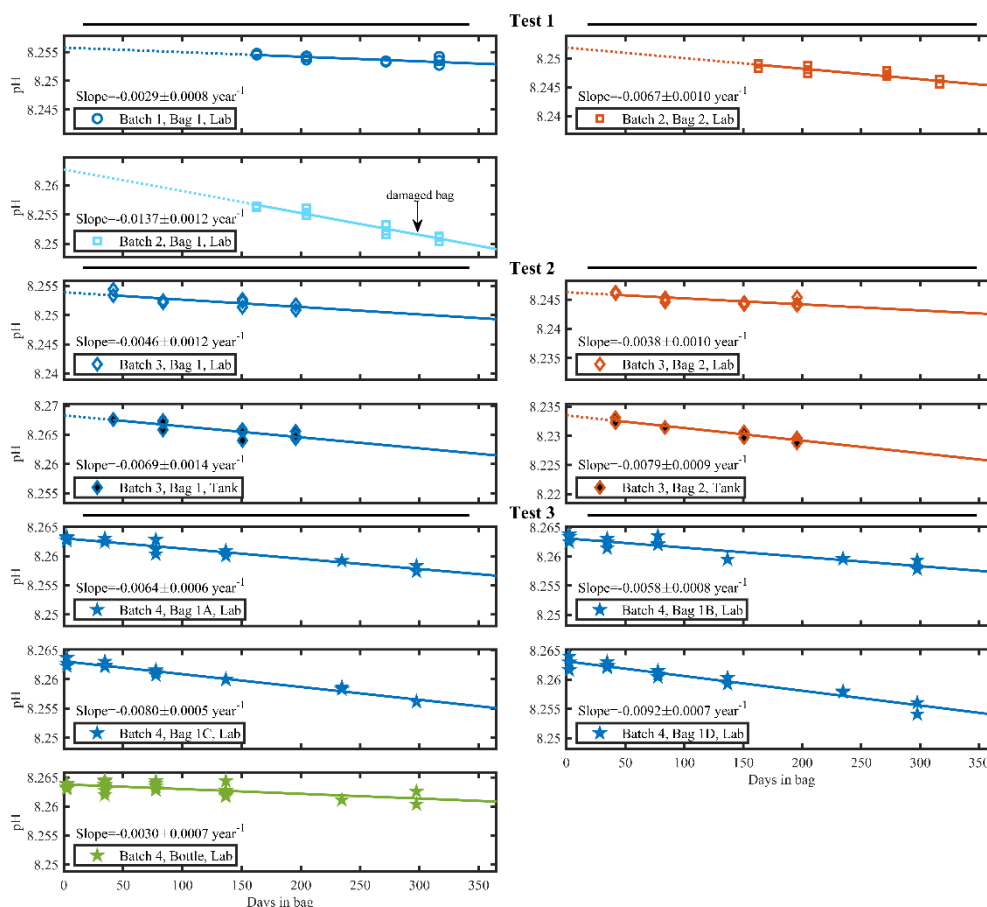

143 Measurements of tris batches 1 and 2 made in the first 150 days have been removed from the data set due to
144 procedural changes made to the spectrophotometric pH system to correct for problems with temperature equilibration.
145 Following normal practices for spectrophotometric pH measurement, outliers were removed from the data set if the
146 absorbance at 760 nm was above 0.005 or below -0.002 (indicative of a measurement problem, such as a bubble or
147 lamp drift), resulting in the removal of 2 out of 163 measurements. Additionally, outliers were removed from the data
148 set if they were greater than three standard deviations from the mean of a measurement triplicate, where standard
149 deviation is calculated as using all sets of triplicates (1 standard deviation = 0.0004, $n = 55$), resulting in the removal
150 of 2 of 161 remaining measurements. The remaining 159 measurements were used for the analysis presented here. An
151 analysis of variation, or ANOVA, was used to detect the dependence of the results on tris batch, bag/bottle type and
152 storage location. Analysis was performed using MATLAB R2020a and the standard function “`anovan()`.” pH and C_T
153 data are available via the UC San Diego Library Digital Collections (Wolfe et al., 2021).

154 3. Results & Discussion

155 Figure 2 depicts $pH_{tris,20^\circ C}$, stored in either a bag or bottle, as a function of time and is subdivided for tests 1,
156 2, and 3. A negative, linear drift was observed for all bags or bottles. A linear regression was calculated for each
157 experimental condition and, in the cases where measurements at $t = 0$ were removed due to protocol changes described
158 above, the line is extrapolated back to $t = 0$, shown by the dotted line. The measured or extrapolated y-intercept is
159 reported as the initial pH in Table 2. In all tests, trendlines are extrapolated to $t = 365$ days to illustrate observed and

160 predicted drift over the course of a year as shown by the solid line. For ease of visual comparison, the y-axis of each
 161 subplot has an identical pH range of 0.017.
 162

163
 164 **Figure 2: Rates of pH drift in tris buffer.** Bag type 1 is shown in blue (light blue for the damaged bag of type 1), 2 in orange
 165 and bottle in green. Tris batch 1 is depicted as circles, 2 as squares, 3 as diamonds and 4 as stars. Storage location in tank
 166 has a black fill and lab symbols have no fill. The solid line is a linear regression starting at the first included pH measurement
 167 and ending 365 days after the tris was bagged. The dotted line illustrates the extrapolation back to 0 days stored in bag
 168 when measurements at $t = 0$ do not exist. The range of the y-axis scale is fixed at 0.017 pH for all subplots.

169

170 **Table 2: Linear regression statistics from trendlines shown in Fig. 1 and 2. The last row shows the regression statistics for**
 171 **tris from all batches, in either bag type, stored in the lab or test tank. Slope and intercept are shown as mean \pm 95%**
 172 **confidence intervals. * Indicates the outlier (Batch 2, Bag 1, Lab) caused by a damaged bag. The outlier, “Batch 2, Bag 1,**
 173 **lab”, was not used in the “All Batches, All Bags, Lab or Tank” composite. † In all batches, all bags, lab or tank, the slope**
 174 **was calculated with a linear fit of all (non-outlier) tris measurements. The RMSE is the mean RMSE of all (non-outlier)**
 175 **bag fits. ‡ The calculated tris pH was calculated at 20°C; however, this calculated pH is 0.0135 higher than equimolar tris**
 176 **as noted above (DeValls and Dickson, 1998).**

| Batch & Storage Method | Slope (mpH yr ⁻¹) | Intercept (Initial pH) | RMSE (mpH) | r ² | n |
|--|-------------------------------|------------------------|------------|----------------|-----|
| Batch 1, Bag 1, Lab | -2.9 \pm 1.7 | 8.2558 \pm 0.0012 | 0.43 | 0.59 | 12 |
| Batch 2, Bag 1, Lab* | -13.7 \pm 2.7 | 8.2627 \pm 0.0018 | 0.61 | 0.94 | 11 |
| Batch 2, Bag 2, Lab | -6.7 \pm 2.2 | 8.2519 \pm 0.0015 | 0.55 | 0.82 | 12 |
| Batch 3, Bag 1, Lab | -4.6 \pm 2.7 | 8.2539 \pm 0.0010 | 0.62 | 0.62 | 11 |
| Batch 3, Bag 1, Tank | -6.9 \pm 3.2 | 8.2683 \pm 0.0012 | 0.73 | 0.73 | 11 |
| Batch 3, Bag 2, Lab | -3.8 \pm 2.1 | 8.2462 \pm 0.0008 | 0.54 | 0.61 | 12 |
| Batch 3, Bag 2, Tank | -7.9 \pm 2.1 | 8.2335 \pm 0.0008 | 0.44 | 0.92 | 9 |
| Batch 4, Bag 1A, Lab | -6.4 \pm 1.3 | 8.2630 \pm 0.0005 | 0.64 | 0.90 | 14 |

| Calculated tris pH‡ | – | 8.2652 | – | – | – |

177
 178 Only bags from test 3, using tris batch 4 and bag type 1, have direct initial pH measurements and replicate
 179 bags. Initial pH measurements of these 4 bags were 8.2630 \pm 0.0007 (mean \pm standard deviation, n = 12). Importantly,
 180 the very low standard deviation suggests that a single initial pH measurement is representative of all replicate bags
 181 filled with a single tris batch, if the preparation procedure used in test 3 is followed. This inter-bag consistency is
 182 beneficial because it reduces the number of initial pH measurements required when filling multiple bags. There is also
 183 strong agreement in initial pH measurements between bagged and bottled tris in test 3, with the initial pH of bottled
 184 tris 0.0007 higher than bagged tris (8.26327 \pm 0.0004, n = 6). The differences in filling procedure or impurities between
 185 bags and bottles in test 3 appear to have little effect on the initial pH. The mean initial pH of tris batch 4 is 0.002 (n =
 186 5) lower than calculated pH_{tris,20°C} (Fig. A2). This difference between the mean initial pH of tris batch 4 and calculated
 187 pH_{tris,20°C} is similar in direction and magnitude to those reported in other studies: DeGrandpre et al. (2014) reported –
 188 0.0012 \pm 0.0025 and Müller and Rehder (2018) reported -0.002 to -0.008 (measured pH minus pH_{tris,T_C}). With standard
 189 laboratory equipment and off-the-shelf reagents, an uncertainty of 0.006 is expected in prepared tris (Paulsen and
 190 Dickson, 2020). Measurements were also made on Dickson standard tris (batch T35) using the same instrument and
 191 the pH was 0.0019 higher than the calculated pH_{tris,20°C} (n = 2). In tests 1 and 2, the initial pH was extrapolated from
 192 a linear regression. The extrapolated initial pH values are more variable and lower (on average) than those directly

193 measured (Fig. A2). These differences may be a result of the extrapolation or different experimental variables such as
194 the increased rinsing of bags, or the single bag type and storage location used in test 3.

195
196 **Figure 3:** The dots represent every measurement made on a (non-damaged) bag of tris. The dotted line is the “All Bags, All
197 Batches, Lab or Tank” regression. The grey shaded region is the observational 95% confidence interval (CI). The CI is
198 intended to estimate the future pH of a tris bag (with known initial pH and an unmeasured bag specific drift rate). The
199 upper and lower bounds are -0.0028 and -0.0091 pH per year, respectively.

200 Figure 3 depicts a composite of all test results as the change from the initial pH of tris
201 ($\Delta pH = pH_{spec,20^\circ C}^{t=day} - pH_{spec,20^\circ C}^{t=0}$) as a function of time elapsed since bagging. By definition, $\Delta pH = 0$ at $t = 0$. We
202 illustrate these pH changes as ΔmpH ($\Delta pH \times 1000$) due to their small magnitude. A linear regression on all pH
203 measurements, excluding the outlier of “Batch 2, Bag 1, Lab”, of tris stored in bag types 1 or 2, has a slope of -0.0058
204 $\pm 0.0008 \text{ yr}^{-1}$ (mean $\pm 95\%$ C.I.). The outlier (Batch 2, Bag 1, Lab) was excluded due to noticeable damage to the bag
205 (see Fig. A3 in Appendix A), which is believed to have caused it to drift at more than two times the average rate of
206 the other bags. This observation highlights the importance of maintaining bag integrity, particularly during use in the
207 field. For Figure 3, the only comparable example found in the literature is the work of Lai et al. (2018). In this work,
208 Lai et al. (2018) used bagged tris for sensor calibration, with in situ tris measurements made over 150 days. Lai et al.
209 (2018) did not report a drift in the pH of bagged tris over the deployment; however, the reported precision of the
210 SAMI-pH in situ instrument (± 0.003) would not resolve the expected drift shown in our Figure 3. Therefore, the
211 results of Lai et al. (2018) are not inconsistent with our study.

212 A significant increase in C_T was observed for all types of bags and bottles in Experiment 3 (Figure 4). A high
213 correlation between solution pH and C_T was observed, with a slope of $-0.0029 \pm 0.0006 \text{ pH per } 100 \mu\text{mol kg}^{-1}$ ($n =$
214 $14, r^2 = 0.70$), suggesting that the drift in tris pH was primarily driven by an increase in CO_2 . The observed slope
215 agrees closely with a theoretical prediction of a linear decrease in pH of -0.0024 per $100 \mu\text{mol kg}^{-1}$ of C_T added (over
216 the range of C_T observed). The linear decrease was calculated using an ad hoc acid–base equilibrium model of seawater
217 including tris in addition to the CO_2 and other minor acid–base systems. There are two possible sources of the

218 increasing C_T : gas exchange of CO_2 with the environment and microbial respiration within the storage vessel. Gas
219 exchange should not be a significant source of CO_2 for tris stored in a borosilicate bottle, as this is the standard
220 equipment used to store seawater CO_2 and tris buffers and has been designed to minimize gas exchange (Dickson et
221 al. 2007). Therefore, it is likely that respiration was the primary driver for the increase in C_T for tris stored in bottles.
222 On average, pH drift of tris stored in bags was larger than that in the standard bottle (Figure 2), indicating either an
223 additional source of CO_2 from gas exchange, or larger amounts of respiration. Distinguishing between these two
224 theorized sources would require measurements of additional parameters such as dissolved organic carbon.

225

226 **Figure 4: pH plotted against C_T shows a linear relationship between the two parameters in tris buffer with a slope of $-$**
227 **0.0029 pH for every $100 \mu\text{mol kg}^{-1}$ of C_T added. The measurements shown are from three sampling occurrences between**
228 **$130\text{--}300$ days stored on bags and bottles used in Test 3. Only two measurements are shown for “Batch 4, Bag 1D, Lab”**
229 **because it ran empty before C_T were made.**

230 The pH stability of tris could be improved by reducing either source of C_T : gas exchange or microbial
231 respiration. For bags, CO_2 may diffuse through the fittings, gasket, or bag walls, particularly if damaged. The relatively
232 small breaks in the aluminium foil layer caused “Batch 2, Bag 1, Lab” to drift more than twice as fast as the average
233 bag. Storage bag, fitting, and gasket material, as well as careful handling, are therefore important factors in minimizing
234 gas exchange. For example, silicone is permeable to CO_2 , and thus could have been a path of gas exchange into the
235 tris for this experiment. As noted above, Nemzer and Dickson (2005) found an almost negligible drift of 0.5 mpH yr^{-1}
236 1 in bottled tris. Our bottled tris drifted at -3.0 mpH yr^{-1} ($n = 10$ bottles measured over 161 days), approximately half
237 the rate of the tris stored in bags. While -3.0 mpH yr^{-1} is near the detection limit of our measurements, it suggests that
238 the bottling protocol used in this study was not as well controlled as that of Nemzer and Dickson (2005). For example,

239 the Dickson lab regularly uses an annealing oven to combust all trace organic films that may persist on glass bottles,
240 but in our study, bottles were not annealed. Although bags cannot be annealed, future steps that may be worth
241 consideration to reduce microbial respiration in bags include addition of a biocide to the tris solution, acid cleaning
242 the bags, and using ultraviolet light to remove organics from the ultrapure water used to prepare tris. There are some
243 disadvantages to these proposed steps. Addition of a biocide may not be ideal for use in sensitive environments if the
244 tris is discharged after use and would alter the composition of the solution slightly. While rinsing or prolonged soaking
245 of the bags with an acid may help to remove organics, it is unclear if it would have negative effects on the integrity of
246 the bags.

247 Both bag type 1 and 2 experienced problems with structural integrity during this experiment. A single type 2
248 bag experienced delamination of exterior bag layers when stored submerged in seawater, causing the eventual tearing
249 and failure of the bag when handling. Bag type 2 was not used in test 3 due to this failure. It should be noted that other
250 studies successfully used bag type 2 submerged the bag in seawater for less time than in this experiment (Sayles and
251 Eck, 2009; Aßmann et al., 2011; Wang et al., 2015). A single bag type 1 had the subtler problem of small breaks in
252 the aluminium foil bag layer, likely causing an increased pH drift rate. In non-damaged bags, factors such as bag
253 type/bottle, lab/tank storage, or tris batch did not have statistically significant (p -value < 0.05) correlations with the
254 pH drift of tris (p -values 0.12, 0.11 and 0.09, respectively). The results of the ANOVA support that tris can be held in
255 bag type 1 or 2 and stored in a lab or tank and the pH will drift similarly regardless of storage method for up to 300
256 days. Additional bag types could be tested, such as bags made by Pollution Measurement Corp. used by Lai et al.
257 (2018) or Scholle DuraShield used by Takeshita et al. (2015).

258 4. Conclusions

259 This article describes our characterization of the stability of tris buffer in artificial seawater when stored in
260 flexible and purportedly gas-impermeable bags. Several different tests, initiated over the course of a year and a half
261 and lasting up to 300 days, exhibited average drift rates of -5.8 mpH yr^{-1} . In comparison, tris stored in standard
262 borosilicate bottles was shown to have a drift rate of -3.0 mpH yr^{-1} . For yearlong deployments, an expected pH change
263 of -0.0058 is well below the weather quality threshold of 0.02 pH units. This low drift rate demonstrates the value of
264 bagged tris for in situ validation of autonomous pH sensors (regardless of sensor operating principles), particularly in
265 highly dynamic areas where repeatability of calibration based on discrete samples is challenging. Given the thorough
266 characterization of tris over wide ranges of environmental variables, this contribution can aid in the traceability and
267 intercomparability of pH sensor measurements.

268 Periodic measurement of bagged tris in situ would allow for detection of sensor drift. Most in situ pH sensors
269 are deployed in the euphotic zone which allows for biofouling and sedimentation in coastal areas, leading to sensor
270 drift (Bresnahan et al., 2014) that could be identified and potentially corrected. Such periodic calibration/validation
271 would aid in identifying sensor issues and allow for greater consistency and continuity between a timeseries and
272 planned or vicarious crossovers where an automated calibration can be used to augment or replace pre- and post-
273 deployment calibrations/validations.

274 **Author contribution**

275 WW performed formal analysis, visualization, and writing – original draft preparation. KS and TW contributed
276 to investigation and writing – review & editing. PB, YT, and TM contributed to funding acquisition, conceptualization,
277 formal analysis, and writing – review & editing.

278 **Competing interests**

279 The authors declare that they have no conflict of interest.

280 **Data availability**

281 pH and C_T data are available via the UC San Diego Library Digital Collections (Wolfe et al., 2021).

282 **Acknowledgements**

283 We thank May-Linn Paulsen and Andrew Dickson lab for sharing their tris expertise throughout this project.
284 We thank the National Science Foundation Ocean Technology and Interdisciplinary Coordination (NSF-OTIC
285 1736905 and NSF-OTIC 1736864) and the David and Lucile Packard Foundation for supporting this work.
