Keywords: wind waves, current, Doppler shift

Abstract

It is important to investigate the effects of current on wind waves, called the Doppler shift, both at normal and extreme high wind speeds. Three different types of wind-wave tanks along with a fan and pump are used to demonstrate wind waves and currents in laboratories at Kyoto University, Japan, Kindai University, Japan, and the Institute of Applied Physics, Russian Academy of Sciences, Russia. Profiles of the wind and current velocities and the water-level fluctuation are measured. The wave frequency, wavelength, and phase velocity of the significant waves are calculated, and the water velocities at the water surface and in the bulk of the water are also estimated by the current distribution. The study investigated 27 cases with carrying winds, waves, and currents, at wind speeds ranging from 7 to 67 m s⁻¹. At normal wind speeds under 30 m s⁻¹, wave frequency, wavelength, and phase velocity depend on wind speed and fetch. The effect of the Doppler shift is confirmed at normal wind speeds, i.e., the significant waves are accelerated by the surface current. The phase velocity can be represented as the sum of the surface current and artificial phase velocity, which is estimated by the dispersion relation of the deep-water waves. At extreme high wind speeds, over 30 m s⁻¹, a similar Doppler shift is observed as under the conditions of normal wind speeds. This suggests that the Doppler shift is an adequate model for representing the acceleration of wind

35 waves by current, not only for the wind waves at normal wind speeds but also for those
36 with intensive breaking at extreme high wind speeds. A weakly nonlinear model of
37 surface waves at a shear flow is developed. It is shown that it describes well the
38 dispersion properties of not only small-amplitude waves but also strongly nonlinear and
39 even breaking waves, typical for extreme wind conditions (over 30 m s^{-1}).

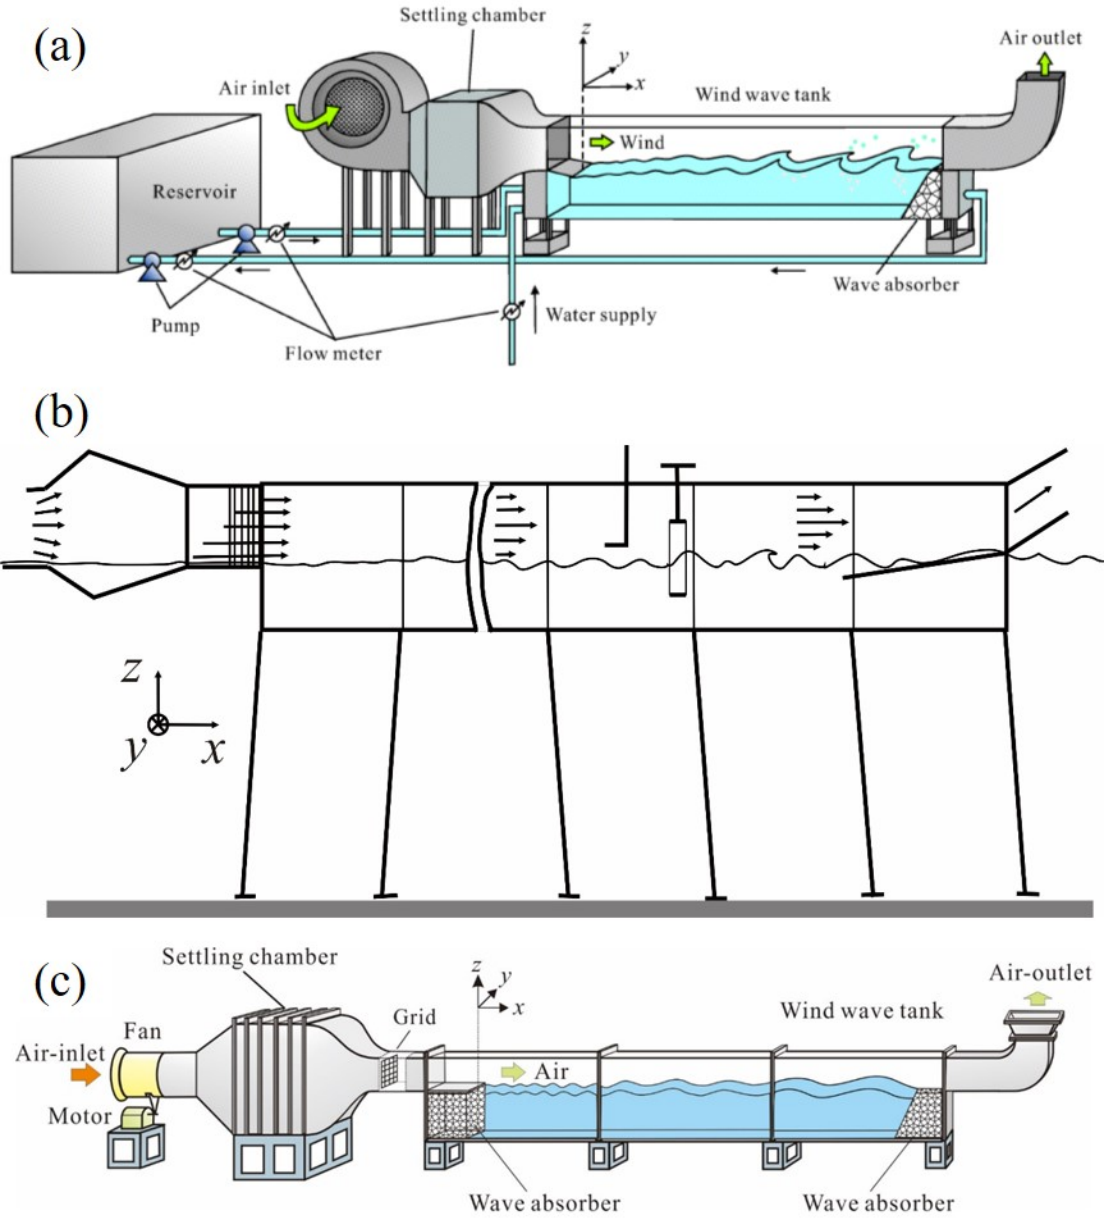

40

41 **1. Introduction**

42 The oceans flow constantly, depending on the rotation of the Earth, tides, topography,
43 and wind shear. High-speed continuous ocean flows are called currents. Although the
44 mean surface velocity of the ocean is approximately 0.1 m s^{-1} , the maximum current
45 surface velocity is more than 1 m s^{-1} (e.g., Kawabe, 1988; Kelly et al., 2001). The
46 interaction between the current and wind waves generated by wind shear have been
47 investigated in several studies. The acceleration effects of the current on wind waves,
48 called the Doppler shift; the effects of the current on the momentum and heat transfer
49 across the sea surface; and the modeling of waves and currents in the Gulf Stream have
50 been the subject of experimental and numerical investigations (e.g., Dawe and Thompson,
51 2006; Kara et al., 2007; Fan et al., 2009; Shi and Bourassa, 2019). Thus, wind waves
52 follow the dispersion relationship and Doppler shift effect at normal wind speeds.
53 However, these studies were performed at normal wind speeds only, and few studies have
54 been conducted at extreme high wind speeds, for which the threshold velocity is $30 - 35$
55 m s^{-1} , representing the regime shift of the air-sea momentum, heat, and mass transport
56 (Powell et al., 2003; Donelan et al., 2004; Takagaki et al., 2012, 2016; Troitskaya et al.,
57 2012, 2020; Iwano et al., 2013; Krall and Jähne, 2014; Komori et al., 2018; Krall et al.,
58 2019). At such extremely high wind speeds, the water surface is intensively broken by
59 the strong wind shear, along with the foam layer, dispersed droplets, and entrained
60 bubbles (e.g. Donelan et al., 2004; Troitskaya et al., 2012, 2017, 2018a, 2018b; Takagaki
61 et al., 2012, 2016; Holthuijsen et al., 2012). It is unclear if the properties of wind waves
62 and the surface foam layer at extremely high wind speeds are similar to those at normal
63 wind speeds. Furthermore, in a hurricane, the local ocean flows may be unusually strong,
64 change rapidly, and strongly affect wind waves. However, the effects of the current on
65 wind waves have not yet been clarified.

66 Therefore, the purpose of this study is to investigate the effects of the current on wind
67 waves in strong winds through the application of three different types of wind-wave tanks,
68 along with a pump.

 74
 75 **2. Experiment**

76 **2.1. Equipment and measurement methods**

77 Wind-wave tanks at Kyoto University, Japan and the Institute of Applied Physics,
 78 Russian Academy of Sciences (IAP RAS) were used in the experiments (Figs. 1a, 1b).
 79 For the tank at Kyoto University, the glass test section was 15 m long, 0.8 m wide, and 1.6
 80 m high. The water depth D was set at 0.8 m. For the tank at IAP RAS, the test section in

81 the air side was 15 m long, 0.4 m wide, and 0.4 m high. The water depth D was set at 1.5
82 m. The wind was set to blow over the filtered tap water in these tanks, generating wind
83 waves. The wind speeds ranged from 4.7 to 43 m s⁻¹ and from 8.5 to 21 m s⁻¹ in the tanks
84 at Kyoto and IAP RAS, respectively. Measurements of the wind speeds, water-level
85 fluctuation, and current were carried out 6.5 m downstream from the edge ($x = 0$ m) in
86 both the Kyoto and IAP RAS tanks. Here, the x , y , and z coordinates are referred to as the
87 streamwise, spanwise, and vertical directions, respectively, with the origin located at the
88 center of the edge of the entrance plate. Additionally, the fetch (x) is defined as the
89 distance between the origin and measurement point ($x = 6.5$ m).

90 In Kyoto, a laser Doppler anemometer (Dantec Dynamics LDA) and phase Doppler
91 anemometer (Dantec Dynamics PDA) were used to measure the wind velocity fluctuation.
92 A high-power multi-line argon-ion (Ar⁺) laser (Lexel model 95-7; laser wavelengths of
93 488.0 and 514.5 nm) with a power of 3 W was used. The Ar⁺ laser beam was shot through
94 the sidewall (glass) of the tank. Scattered particles with a diameter of approximately 1 μ m
95 were produced by a fog generator (Dantec Dynamics F2010 Plus) and were fed into the
96 air flow over the waves (see Takagaki et al. (2012) and Komori et al. (2018) for details).
97 The wind speed values (U_{10}) at a height of 10 m height above the ocean and the friction
98 velocity (u^*) were estimated by the eddy correlation method, by which the mean velocity
99 (U) and the Reynolds stress ($-uv$) in air were measured. The u^* was estimated by an eddy
100 correlation method as $u^* = (-\langle uv \rangle)^{1/2}$, because the shear stress at the interface (τ) was
101 defined by $\tau = \rho u^{*2} = \rho C_D U_{10}^2$. The value of $(-\langle uv \rangle)^{1/2}$ was estimated by extrapolating the
102 measured values of the Reynolds stress to the mean surface of $z = 0$ m. The U_{10} was
103 estimated by the log-law: $U_{10} - U_{\min} = u^*/\kappa \ln(z_{10}/z_{\min})$, where U_{\min} is the air velocity
104 nearest the water surface (z_{\min}) and z_{10} is 10 m. Moreover, the drag coefficient C_D was
105 estimated by $C_D = (u^*/U_{10})^2$.

106 Water level fluctuations were measured using resistance-type wave gauges (Kenek
107 CHT4-HR60BNC) in Kyoto. The resistance wire was placed into the water, and the
108 electrical resistance at the instantaneous water level was recorded at 500 Hz for 600 s
109 using a digital recorder (Sony EX-UT10). The energy of the wind waves (E) was
110 estimated by integrating the spectrum of the water-level fluctuations over the frequency
111 (f). The values of the wavelength (L_s) and phase velocity (C_s) were estimated using the
112 cross-spectrum method (e.g., Takagaki et al., 2017) (see the detail in Appendix). The
113 current was measured using the same LDA system.

114 In IAP RAS, a hot-wire anemometer (E+E Elektronic EE75) was used to measure the
115 representative mean wind velocity at $x = 0.5$ m and $z = 0.2$ m. The three wind velocities
116 (U_{10} , u^* , U_∞) at $x = 6.5$ m were taken from Troitskaya et al. (2012) by a Pitot tube. Here,

117 U_∞ is the freestream wind speed. The u^* was estimated by a profile method considering
 118 the profiles in the constant flux layer and the wake region:

$$U_\infty - U(z) = u^* \left(-\frac{1}{\kappa} \ln(z/\delta) + \alpha \right); z/\delta < 0.15, \quad (1)$$

$$U_\infty - U(z) = \beta u^* (1 - z/\delta)^2; z/\delta > 0.15, \quad (2)$$

119
 120 respectively. Here, δ is the boundary layer thickness, and α and β are the constant values
 121 that depend on flow fields and are calibrated at low wind speeds without the dispersed
 122 droplets. At extremely high wind speeds, measuring the profile in the constant flux layer
 123 (Eq. 1) is difficult because of the large waves; thus, using β measured at low wind speeds,
 124 u^* is estimated by Eq. (2). The value of U_{10} is estimated by Eq. (1) at $z_{10} = 10$ m with
 125 measured α at normal wind speeds. The value of C_D is estimated by $C_D = (u^*/U_{10})^2$.
 126 Although the measurement methods for u^* , U_{10} , and C_D in IAP RAS and Kyoto are
 127 different, the values approximately correspond to each other (see Troitskaya et al. (2012)
 128 and Takagaki et al. (2012)).
 129

130 The water-level fluctuations were measured using three handmade capacitive-type
 131 wave gauges in IAP RAS. Three wires formed a triangle with 25 mm on a side
 132 (x -directional distance between wires Δx is 21.7 mm). The wires were placed in the water,
 133 and the output voltages at the instantaneous water level were recorded at 200 Hz for 5400
 134 s using a digital recorder through an AD converter (L-Card E14-140). The values (E , f_m ,
 135 H_s , T_s , C_s , and L_s) were estimated by the same manner as in Kyoto tank. The current was
 136 measured through acoustic Doppler velocimetry (Nortec AS) at $x = 6.5$ m and $z = -10$,
 137 -30 , -50 , -100 , -150 , -220 , and -380 mm (see Troitskaya et al. (2012) for details).
 138

139 **2.2. Artificial current experiments at Kindai University**

140 Additional experiments were performed using a wind-wave tank at Kindai
 141 University with a glass test section 6.5 m long, 0.3 m wide, and 0.8 m high (Fig. 1c) (e.g.
 142 Takagaki et al., 2020). The water depth D was set at 0.49 m. A Pitot tube (Okano Works,
 143 LK-0) and differential manometers (Delta Ohm HD402T) were used to measure the mean
 144 wind velocity. The values of u^* , U_{10} , and C_D (Cases 21-27) were estimated using U_∞ by
 145 the empirical curve by Iwano et al. (2013), which was proposed by the eddy correlation
 146 method used in Kyoto (see section 2.1).

147 The water level fluctuations were measured using resistance-type wave gauges
 148 (Kenek CHT4-HR60BNC). To measure L_s and C_s , another wave gauge was fixed
 149 downstream at $\Delta x = 0.02$ m, where Δx is the interval between the two wave gauges. The
 150 values (E , f_m , H_s , T_s , C_s , and L_s) were estimated by the same manner as in Kyoto tank.
 151 The current was then measured through electromagnetic velocimetry (Kenek LP3100)

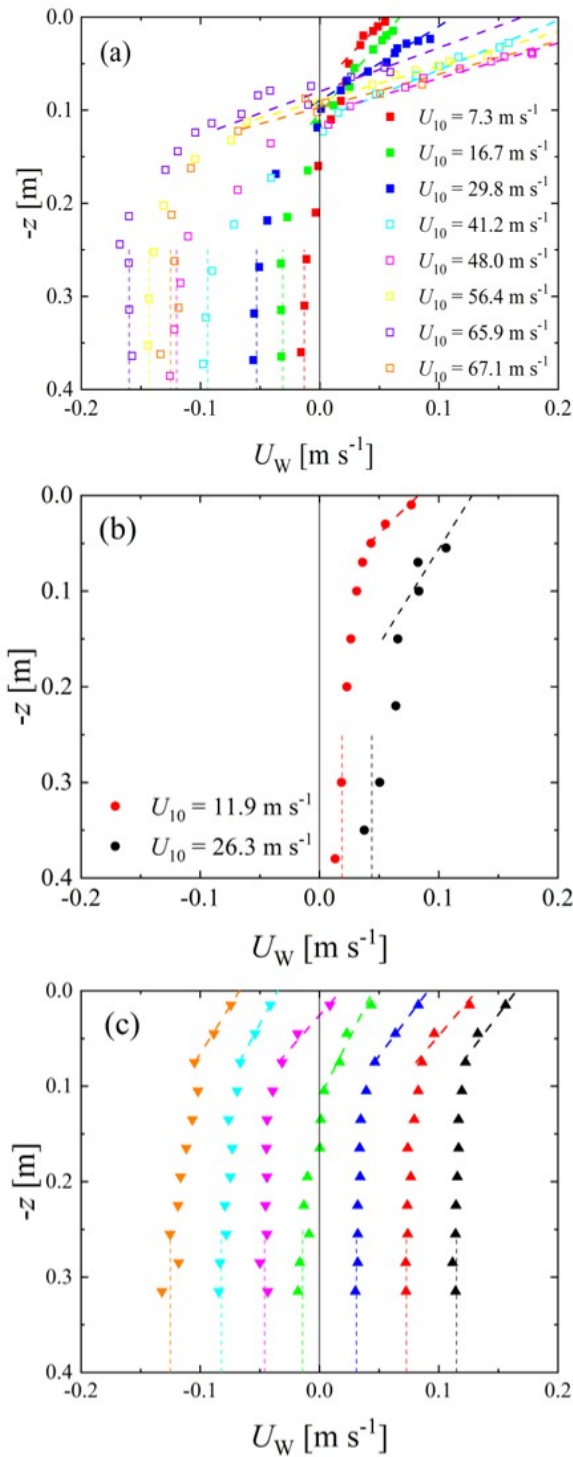

152 with a probe (Kenek LPT-200-09PS) at $x = 4.0$ m. The probe sensing station was 22 mm
153 long with a diameter of 9 mm. The measurements were performed at $z = -15$ to -315 mm
154 at 30 mm intervals. The sampling frequency was 8 Hz, and the sampling time was 180 s.
155

156 **3. Results and discussion**

157 **3.1. Waves and current**

158 Figure 2 shows the vertical distributions of the streamwise water velocity. The
159 water velocities in the three different wind-wave tanks at Kyoto University, Kindai
160 University, and IAP RAS are separately shown in each subfigure. In Fig. 2a, the bulk
161 velocity of water U_{BULK} shows negative values ($U_{\text{BULK}} = -0.16$ to -0.01 m s⁻¹) at Kyoto
162 University, which is generated as the counterflow against the Stokes drift at the wavy
163 water surface. In Fig. 2b, the bulk velocity of water demonstrates positive values (U_{BULK}
164 $= 0.019$ to 0.044 m/s) at IAP RAS, because the wind-wave flume is submerged; thus, the
165 Stokes drift on the wavy water surface does not provide the counterflow for the bulk
166 water, unlike in the closed tank at Kyoto University. From Fig. 2c, it is clear that the bulk
167 velocities of the water vary in each case at Kindai University with the use of the pump.
168 Furthermore, the water bulk velocities change from negative to positive ($U_{\text{BULK}} = -0.13$
169 to -0.17 m s⁻¹). The bulk velocities of water were defined as the mean velocity with $z =$
170 -0.4 to -0.25 m (see dotted lines in Fig. 2), and the velocities are listed in Table 1.
171 Experiments were performed under 27 different conditions, with the bulk velocity of
172 water provided in the three different wind-wave tanks. The surface velocities of water,
173 U_{SURF} , also varied in the three tanks with respect to wind speed (see Fig. 2). The U_{SURF}
174 values were estimated by the linear extrapolation lines (dashed lines) as the water velocity
175 at the surface ($z = 0$ m) shown in Fig. 2, and the velocities are listed in Table 1.

176 Figure 3 shows the wind-velocity dependency of the wave frequency f_m ,
177 wavelength L_S , phase velocity C_S , surface velocity of water U_{SURF} , and bulk velocity of
178 water U_{BULK} . From Figs. 3a–3c, it is clear that both the Kyoto and IAP RAS data
179 demonstrate that the wind waves develop with wind shear. Although f_m in both cases
180 correspond to each other, L_S and C_S in IAP RAS are different from those in Kyoto. The
181 disagreement might be caused by the difference in the wind-wave development or
182 Doppler effect; this is discussed below. From Figs. 3d and 3e, U_{SURF} and U_{BULK} increase
183 with an increase in U_{10} in IAP RAS. However, in Kyoto, U_{SURF} increases, but U_{BULK}
184 decreases with an increase in U_{10} . Moreover, U_{SURF} in IAP RAS corresponds to U_{SURF} in
185 Kyoto. This is because the Stokes drift generated by the wind waves, rather than the
186 current, is significant. For the Kindai data, although f_m , U_{SURF} , and U_{BULK} vary, L_S and C_S
187 are concentrated at single points at $L_S = 0.1$ m and $C_S = 0.4$ m s⁻¹, respectively.

188

189 **Figure 2.** Vertical distributions of water-flow velocity; (a) Kyoto University, (b) IAP RAS, and (c)

190 Kindai University. In (c), plots indicate cases 21–27 starting from right. Dotted and dashed lines

191 indicate the lines used to estimate U_{BULK} and U_{SURF} , respectively. Open symbols show the

192 high-wind-speed cases.

193 **TABLE 1.** Wind and wind-wave properties. F : fetch; N_{PUMP} : pump inverter frequency; U_{∞} :
194 freestream wind speed; u^* : friction velocity of air; U_{10} : wind speed at 10 m above the sea surface;
195 U_{SURF} : surface flow velocity of water; U_{BULK} : bulk flow velocity of water; C_D : drag coefficient; H_s :
196 significant wave height; T_s : significant wave period; E : wave energy; f_m : significant frequency; C_s :
197 phase velocity; L_s : significant wave length; $C_{s\text{-theor-l}}$: phase velocity predicted by theoretical linear
198 model; $C_{s\text{-theor-nl}}$: phase velocity predicted by theoretical nonlinear model. The values of u^* , U_{10} , and
199 C_D in Kindai were estimated using the empirical curves by Iwano et al. (2013) from U_{∞} . Superscripts \dagger
200 and $\dagger\dagger$ indicate the artificial following and opposing flows, respectively.

201

202

203 This shows that the intensity and direction of the current do not significantly affect L_s and
204 C_s but do affect f_m and U_{SURF} . Thus, this implies that the present artificial current changes
205 the water flow dramatically but does not affect the development of the wind waves.

206

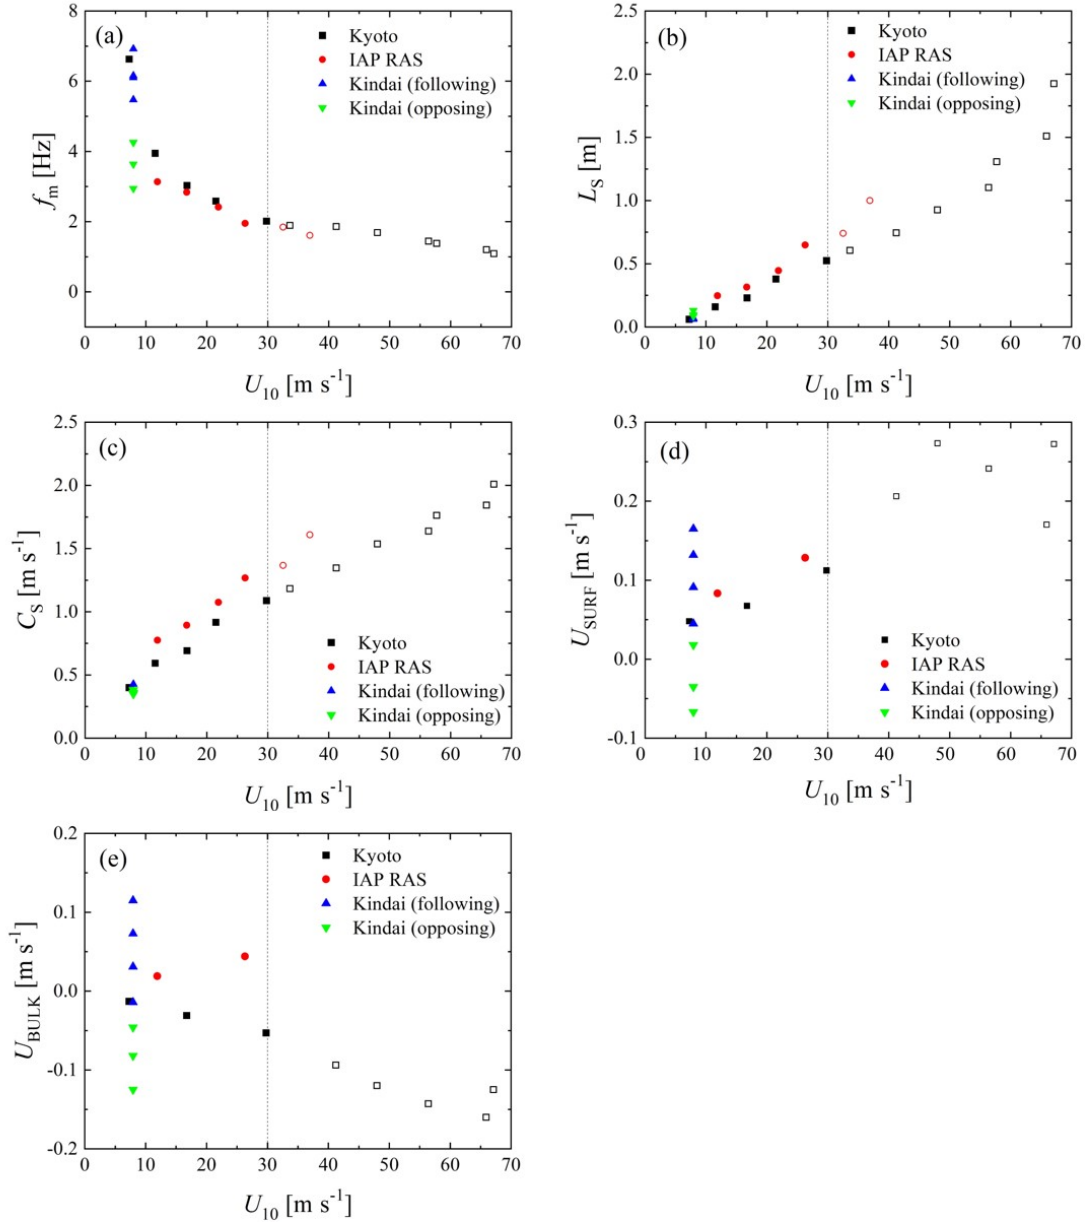

207

208

209

210

Figure 4 shows the dispersion relation and demonstrates that the Kindai data points depend on the variation in the water velocity of the artificial current. The plots for the Kyoto University and IAP RAS cases at normal wind speeds (solid symbols) are concentrated above the solid curve, showing the dispersion relation of the deep-water waves ($\omega^2 = gk$). Meanwhile, the plots for extreme high wind speeds (open symbols) are

211

212 **Figure 3.** Relationships between U_{10} and (a) significant frequency f_m , (b) significant wave length L_s ,
 213 (c) phase velocity C_s , (d) surface velocity of water U_{SURF} , and (e) bulk velocity of water U_{BULK} . Open
 214 symbols show the high-wind-speed cases.

215

216 also concentrated above the solid curve. This implies that the wind waves, along with the
 217 intensive breaking at extreme high wind speeds, are dependent on the Doppler shift. To
 218 investigate the phase velocity trend, Fig. 5 shows the ratio of the measured phase velocity
 219 C_s to the phase velocity $C_{s,0}$ estimated by the dispersion relation of the deep-water waves
 220 ($C_{s,0} = (gL_s/2\pi)^{1/2}$) against the wind velocity. From the figure, the ratios at the normal

221

222 **Figure 4.** Dispersion relation between angular frequency ω and wave number k . Open symbols show
 223 the high-wind-speed cases. Curve shows the dispersion relation of the deep-water waves ($\omega^2 = gk$).

224

225

226 **Figure 5.** Relationship between the freestream wind speed and phase velocity C_s . The C_s is
 227 normalized by phase velocity $C_{s,0}$ without the Doppler effect, estimated by the dispersion relation of
 228 the deep-water waves ($C_{s,0} = (gL_s/2\pi)^{1/2}$). Open symbols show the high-wind-speed cases.

229 wind speeds assume a constant value (~ 1.21 in Kyoto or ~ 1.27 in IAP RAS). Moreover,
 230 the ratios at the extreme high wind speeds take similar values of 1.23 and 1.28 for Kyoto
 231 or IAP RAS, respectively. This implies that the phase velocities at extreme high wind
 232 speeds are accelerated by the current just as those at normal wind speeds. However, the
 233 Kindai values are scattered and increase in the following cases and decrease in the
 234 opposing cases. It is clear that the artificial current accelerates (or decelerates) the phase
 235 velocity.

236 To interpret the relationship among the measured phase velocity C_S , first phase
 237 velocity $C_{S,0}$ estimated by the dispersion relation, and water velocity, two types of phase
 238 velocity were evaluated: the sum of $C_{S,0}$ and surface velocity of water U_{SURF} and the sum
 239 of $C_{S,0}$ and bulk velocity of water U_{BULK} . Figure 6 shows the relationship between C_S and
 240 (a) $C_{S,0} + U_{SURF}$, and (b) $C_{S,0} + U_{BULK}$. In Fig. 6a, we can see that the Doppler shift is
 241 confirmed at the normal wind speeds, i.e., the significant waves are accelerated by the
 242 surface flow, and the real phase velocity can be represented as the sum of the velocity of
 243 the surface flow and the virtual phase velocity, which is estimated by the dispersion
 244 relation of the deep-water waves. At extreme high wind speeds over 30 m s^{-1} , a similar
 245 Doppler shift is observed as under the conditions of normal wind speeds, as seen in Fig.
 246 6a. Meanwhile, in Fig. 6b, although C_S corresponds to $C_{S,0} + U_{BULK}$ at low phase
 247 velocities, C_S assumes values larger than $C_{S,0} + U_{BULK}$ at high phase velocities. This
 248 suggests that the Doppler shift is an adequate model for representing the acceleration of
 249 the wind waves by the current, not only for the wind waves at normal wind speeds but
 250 also for those with intensive breaking at extreme high wind speeds. Moreover, the
 251 Doppler shift of wind waves occurs due to a very thin surface flow, as the correlation
 252 between C_S and $C_{S,0} + U_{SURF}$ is higher than the correlation between C_S and $C_{S,0} + U_{BULK}$.

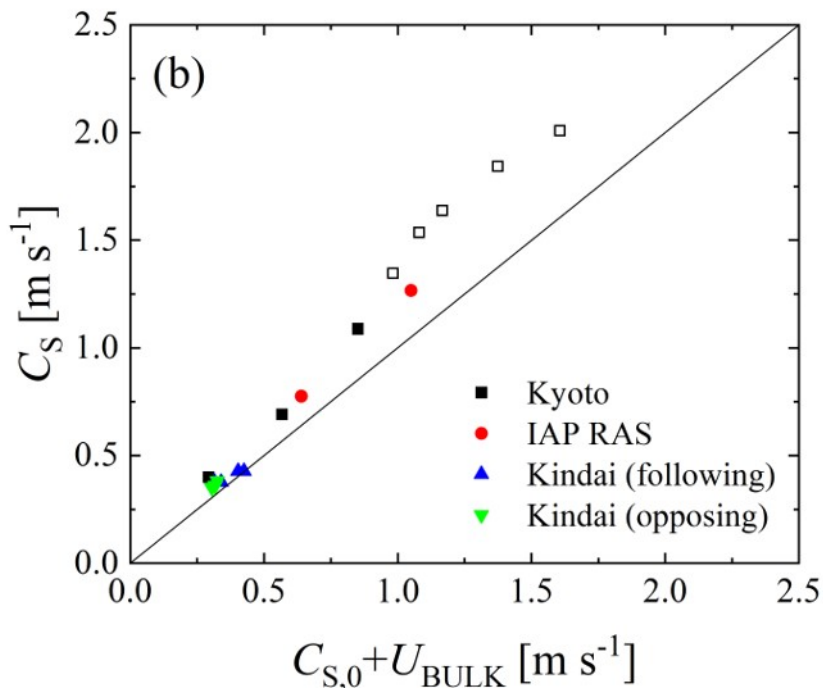

253

254 **3.2. The theoretical model of waves at the shear flow**

255 The parameters of the observed Doppler shift can be explained more precisely
 256 within the theoretical model of the capillary-gravity waves at the surface of the water
 257 flows with the velocity profiles prescribed by the experimental data, which are plotted in
 258 Fig. 2a–c. Because the dominant wind wave propagates along the wave and water flows,
 259 we will consider the 2D-wave model in the 2D flow. This flow is described by the system
 260 of 2D Euler equations:

$$261 \quad \frac{\partial u}{\partial t} + u \frac{\partial u}{\partial x} + w \frac{\partial u}{\partial z} + \frac{1}{\rho} \frac{\partial p}{\partial x} = 0, \quad (3)$$

$$262 \quad \frac{\partial w}{\partial t} + u \frac{\partial w}{\partial x} + w \frac{\partial w}{\partial z} + \frac{1}{\rho} \frac{\partial p}{\partial z} = -g,$$

263

264 **Figure 6.** Relationship between phase velocity C_S and (a) sum of $C_{S,0}$ and surface velocity of water
 265 U_{SURF} , and (b) sum of $C_{S,0}$ and bulk velocity of water U_{BULK} . Open symbols show the high-wind-speed
 266 cases.

267

268 and the condition of non-compressibility:

$$269 \quad \frac{\partial u}{\partial x} + \frac{\partial w}{\partial z} = 0, \quad (4)$$

270 with the kinematical

$$271 \quad \frac{\partial \eta}{\partial t} + u \frac{\partial \eta}{\partial x} = w \Big|_{z=\eta(x,t)} \quad (5)$$

272 and dynamical boundary conditions

$$273 \quad p \Big|_{z=\eta(x,t)} = 0 \quad (6)$$

274 at the water surface. Here, u and w are the horizontal and vertical velocity components, p
 275 is the water pressure, x and z are the horizontal and upward vertical coordinates, g is the
 276 gravity acceleration, and ρ is the water density. The boundary condition at the bottom of
 277 the channel is $w \Big|_{z=-D} = 0$. It should be noted that the water depth in almost all the
 278 experimental runs exceeded half of the wavelength of the dominant waves (see Table 1).
 279 In this case, the deep-water approximation is applicable for describing the surface waves,
 280 and the boundary condition of the wave field vanishing with the distance from the water
 281 surface can also be used.

282 Because the fluid motion under consideration is 2D, the stream function can be
 283 introduced as follows:

$$284 \quad u = \frac{\partial \psi}{\partial z}; w = -\frac{\partial \psi}{\partial x}. \quad (7)$$

285 To derive the linear dispersion relation for the surface waves at the plane shear flow with
 286 the horizontal velocity profile $U_w(z)$, we consider the solution to Eqs. (3, 4) in terms of the
 287 stream function as the sum of the undisturbed state with steady shear flow and
 288 small-amplitude disturbances. Then, the stream function ψ and pressure p are as follows:

$$289 \quad \psi(x, z, t) = \int_{z_1}^z U_w(z_1) dz_1 + \varepsilon \psi_1(x, z, t); \quad (8)$$

$$290 \quad p(x, z, t) = -\rho g z + \varepsilon p_1(x, z, t), \quad (9)$$

291 where $\varepsilon \ll 1$, and the water elevation value is also the order of ε , namely $\varepsilon \eta_1(x, t)$.

292 In the linear approximation in ε , the system of Eqs. (3, 4) and the boundary
 293 conditions of Eqs. (5, 6) take the form:

$$\begin{aligned}
294 \quad & \left(\frac{\partial}{\partial t} + \frac{U_w(z)\partial}{\partial x} \right) \left(\frac{\partial^2 \psi_1}{\partial x^2} + \frac{\partial^2 \psi_1}{\partial z^2} \right) - \frac{\partial \psi_1}{\partial x} \frac{d^2 U_w(z)}{dz^2} = 0, \\
295 \quad & \frac{\partial \eta_1}{\partial t} + U_w(0) \frac{\partial \eta_1}{\partial x} = - \frac{\partial \psi_1}{\partial x} \Big|_{z=0}, \\
296 \quad & \frac{\partial p_1}{\partial x} \Big|_{z=0} - \rho g \frac{\partial \eta_1}{\partial x} = 0, \\
297 \quad & \psi_1 \Big|_{z=-D} = 0.
\end{aligned} \tag{10}$$

298 Excluding p_1 with use of the first equation of the system in Eq. (3) and eliminating η_1
299 yields one boundary condition at the water surface for ψ_1 :

$$300 \quad \left[\left(\frac{\partial}{\partial t} + \frac{U_w(0)\partial}{\partial x} \right)^2 \frac{\partial \psi_1}{\partial z} - \left(\frac{\partial}{\partial t} + U_w(0) \frac{\partial}{\partial x} \right) \frac{\partial \psi_1}{\partial x} \frac{dU_w}{dz} - g \frac{\partial^2 \psi_1}{\partial x^2} \right] \Big|_{z=0} = 0. \tag{11}$$

301 For the harmonic wave disturbance, where

$$302 \quad \psi_1(x, z, t) = \Psi(t) \exp(-i(\omega t - kt)), \tag{12}$$

303 substituting into Eqs. (10, 11) yields the Rayleigh equation for the complex amplitude of
304 the stream function disturbance:

$$305 \quad (\omega - U_w(z)k) \left(\frac{d^2 \Psi_1}{dz^2} - k^2 \Psi_1 \right) + \frac{d^2 U_w(z)}{dz^2} k^2 \Psi_1 = 0, \tag{13}$$

306 with the following boundary condition:

$$307 \quad (\omega - U_w(0)k)^2 \frac{d\Psi_1(0)}{dz} + (\omega - U_w(0)k)k\Psi_1(0) \frac{dU_w(0)}{dz} - k^2 g\Psi_1(0) = 0, \tag{14}$$

$$308 \quad \Psi_1 \Big|_{z \rightarrow -\infty} \rightarrow 0.$$

309 Numerically solving the boundary layer problem for Eq. (13) with the boundary
310 conditions in Eq. (14) enables one to obtain the dispersion relation $\omega(k)$ for the surface
311 waves at the inhomogeneous shear flow. Note that because the phase velocity of the
312 waves significantly exceeded the flow velocity in all experiments (cf. Figs. 2 and 3), the
313 Rayleigh equation did not have a singularity, and the calculated frequency and phase
314 velocity of the wave were real values, i.e., the current was neutral stable.

315 The wave phase velocities $C_{S\text{-theor-1}} = \omega(k)/k$ were calculated for the parameters of
316 those experiments that contained complete information about the course and
317 characteristics of the waves, namely 1, 3, 5, 7, 9, 11, 13–15, 18, and 21–27 from Table 1.
318 The results are presented in Fig. 7a as the measured phase velocity C_s versus calculated
319 phase velocity $C_{S\text{-theor-1}}$. One can see that the model corresponds to the data substantially
320 better than does the model of linear potential waves at the homogeneous current U_{BULK}
321 (compare Fig. 6b). Considering the structure of the wave disturbances of the stream

322

323 **Figure 7.** The measured phase velocity C_S versus theoretical prediction: (a) linear model, and (b)

324

nonlinear model.

325

326

327 **Figure 8.** Vertical velocity profiles (points), their fitting (thin color line), the eigenfunction of the Eq.
 328 (8) with the boundary conditions Eq. (9) (black solid curve), the function e^{kz} (crosses), the function e^{2kz}
 329 (dashed line). The panels (a)-(j) corresponds to the experiments No. 1, 3, 5, 7, 9, 11, 13-15, 18
 330 respectively, the panel (k) corresponds to the experiments No. 21-27.

331

332 function, $\Psi_1(z)$, which was found as the eigenfunction of the boundary problem of Eqs.
 333 (11, 12). The profiles of $\Psi_1(z)$ are presented in Fig. 8. One can see that in all cases the
 334 functions $\Psi_1(z)$ are close to e^{kz} at the background of the mean velocity profiles. Moreover,
 335 for experiments No. 1, 3, 5, 15, and 21–27 (see Fig. 8a, 8b, 8c, 8i, and 8k), the wave field
 336 is concentrated near the surface at a distance less than the scale of the change in the mean
 337 flow, where the flow velocity is approximately equal to U_{SURF} . This explains the good
 338 correlation in these cases of the observed phase velocity with the phase velocity of waves
 339 at the homogeneous current U_{SURF} presented in Fig. 6a. At the same time, for experiments
 340 No. 7, 9, 5, 11, 13, 14, and 18 (see Figs. 8d–8h, and 8j), the scale of the variability of the
 341 flow is significantly smaller than the scale of the wave field. Under these conditions, a
 342 significant difference between the phase velocity of the waves and that given by the linear
 343 dispersion relation can be due to the influence of nonlinearity.

344

345 To estimate the nonlinear addition to the wave phase velocity, we used the results
 346 of the weakly nonlinear theory of surface waves for the current with a constant shear. Of
 347 course, the flow in the experiments of the present work does not have a constant shift, and
 this was considered when obtaining the linear dispersion relation. However, it should be

348 taken into account that the contributions of the n -th harmonic to the nonlinear dispersion
 349 relation are determined by wave fields in the n -power, which have a scale that is n time
 350 smaller than the first harmonic. Additionally, the model of constant shear of the mean
 351 current velocity is already approximately applicable for the 2nd harmonic (see Fig. 8).

352 We use the nonlinear dispersion relation for waves in the current with a constant
 353 shift in the deep-water approximation, which was obtained by Simmen and Saffman
 354 (1985):

$$\begin{aligned}
 355 \quad & (\omega - U_w(0)k)^2 \frac{d\Psi_1(0)}{dz} + (\omega - U_w(0)k)k\Psi_1(0) \frac{dU_w(0)}{dz} - k^2 g\Psi_1(0) = \gamma(ka)^2, \\
 356 \quad & \gamma = \frac{(\omega_0 - U_w(0)k)^2}{2k} \left(1 - \frac{1}{2}\Omega^2 + \left(1 + 2\Omega + \frac{1}{2}\Omega^2 \right)^2 \right), \quad (15) \\
 357 \quad & \Omega = \frac{1}{(\omega_0 - U_w(0)k)} \frac{dU_w(0)}{dz},
 \end{aligned}$$

358 Here, ω_0 is the solution of the linear dispersion equation. Eq. (15) is rewritten in the
 359 notation of this work and formulated in a reference frame in which the surface of the
 360 water has the velocity $U_w(0)$. Note that the linear part of Eq. (15) coincides with Eq. (14).
 361 The results of solving Eq. (15) are presented in Fig. 7b similarly to Fig. 7a as the
 362 measured phase velocity C_S versus calculated phase velocity $C_{S\text{-theor-nl}} = \omega(k)/k$, where
 363 one can see their good agreement with each other. Thus, the wave frequency shift can be
 364 explained by two factors, including the Doppler shift at the mean flow and the nonlinear
 365 frequency shift, while, the latter can also be interpreted in its physical nature as the wave
 366 frequency shift in the presence of its orbital velocities.

367 Recent studies have indicated a regime shift in the momentum, heat, and mass
 368 transfer across an intensive broken wave surface along with the amount of dispersed
 369 droplets and entrained bubbles at extreme high wind speeds over 30 m s^{-1} (e.g., Powell et
 370 al., 2003; Donelan et al., 2004; Takagaki et al., 2012, 2016; Troitskaya et al., 2012; Iwano
 371 et al., 2013; Krall and Jähne, 2014; Komori et al., 2018; Krall et al., 2019). Thus, there is
 372 the possibility of a similar regime shift in the Doppler shift of wind waves by the current
 373 at extreme high wind speeds. However, the present study reveals that such a Doppler shift
 374 is observed as under the conditions of normal wind speeds. In this case, the weakly
 375 nonlinear approximation turns out to be applicable for describing the dispersion
 376 properties of not only small-amplitude waves but also nonlinear and even breaking waves.
 377 This implies that the intensive wave breaking at extreme high wind speeds occurs with
 378 the saturation (or dumping) of the wave height rather than the wavelength. This evidence
 379 might be helpful in investigating and modelling the wind-wave development at extreme
 380 high wind speeds.

381

382 **4. Conclusion**

383 The effects of the current on wind waves were investigated through laboratory
384 experiments in three different wind-wave tanks with a pump at Kyoto University, Japan,
385 Kindai University, Japan, and IAP RAS. The study investigated 27 cases with carrying
386 winds, waves, and currents, at wind speeds ranging from 7–67 m s⁻¹. We observed that the
387 wind waves do not follow the dispersion relation in either the normal or the extremely
388 high wind speeds in the three tanks (Fig. 4)—excluding case 25, in which the artificial
389 current experiment used the Kindai tank. In case 25, U_{SURF} is approximately zero (Fig. 3);
390 thus, the Doppler shift does not occur. Then, using 18 datasets (Kyoto and IAP RAS
391 tanks) (Fig. 5), we found that the ratio of $C_S/C_{S,0}$ is constant at both normal and extremely
392 high wind speeds. Moreover, in the artificial current experiment in Kindai, we observed
393 that the ratio varies (Fig. 5). The evidence from the three tank experiments implies that
394 the same wave-current interaction occurs at normal and extremely high wind speeds.

395 To develop an adequate model for wave-current interaction at normal and
396 extremely high wind speeds, we validated four models (Figs. 6 and 7). At normal wind
397 speeds under 30 m s⁻¹, the wave frequency, wavelength, phase velocity of waves, and
398 surface velocity of the water depended on the wind speed (Fig. 3). However, the bulk
399 velocity of the water showed a dependence on the tank type, i.e., a large tank with a
400 submerged wind-wave flume (IAP RAS) or wind flume above a tank (general type of
401 wind-wave tank) (Kyoto University) (Fig. 3). The effect of the Doppler shift was
402 confirmed at normal wind speeds, i.e., the significant waves were accelerated by the
403 surface flow, and the phase velocity was represented as the sum of the surface velocity of
404 water and the phase velocity, which is estimated by the dispersion relation of the
405 deep-water waves (Fig. 6). At extreme high wind speeds over 30 m s⁻¹, a Doppler shift
406 was observed similar to that under the conditions of normal wind speeds (Figs. 4 and 5).
407 This suggests that the Doppler shift is an adequate model for representing the acceleration
408 of wind waves by the current, not only for the wind waves at normal wind speeds but also
409 for those with intensive breaking at extreme high wind speeds. The data obtained by the
410 artificial current experiments conducted at Kindai University were used to explain how
411 the artificial current accelerates (or decelerates) the significant waves. A weakly
412 nonlinear model of surface waves at a shear flow was developed (Fig. 7). It was shown
413 that it describes well the dispersion properties of not only small-amplitude waves but also
414 strongly nonlinear and even breaking waves, typical for extreme wind conditions, with
415 speeds, U_{10} , exceeding 30 m s⁻¹.

Appendix

446

447

448

449

It is important to estimate the phase velocity and wavelength of the significant wind-waves using the water-level fluctuation data. Here, we explain the method, called as the cross-spectrum method. The water-level fluctuation $\eta(x, t)$ at arbitral location x and time t is shown as the equation:

$$\eta(x, t) = \int_{-\Omega}^{\Omega} A(\omega) e^{i(\omega t - k(\omega)x)} d\omega \quad (\text{A1})$$

450

451

where ω is the angular frequency, $A(\omega)$ is the complex amplitude, and $k(\omega)$ is the

452 wavenumber of waves having ω , Ω is the maximum angular frequency of the surface
 453 waves. $F_\eta(\omega)$ is the Fourier transformation of $\eta(x, t)$ when the measurement time t_m and Ω
 454 are sufficiently large. Using the inverse Fourier transformation of $F_\eta(\omega)$, $\eta(x, t)$ is shown
 455 as:

$$\eta(x, t) = \frac{1}{2\pi} \int_{-\Omega}^{\Omega} F_\eta(\omega) e^{i\omega t} d\omega. \quad (\text{A2})$$

456 Comparing Eqs. (A1, A2), $F_\eta(\omega)$ is $F_\eta(\omega) = 2\pi A(\omega) e^{-ik(\omega)x}$. Assuming that the wind waves
 457 change the shape little between two wave probes set upstream and downstream, we can
 458 set the upstream and downstream water-level fluctuations $\eta_1(t) = \eta(0, t)$ and $\eta_2(t) = \eta(\Delta x,$
 459 $t)$, respectively, with Δx downstream from the first probe. The Fourier transformations
 460 $F_{\eta_1}(\omega)$ and $F_{\eta_2}(\omega)$ for $\eta_1(t)$ and $\eta_2(t)$, respectively, are shown as:

$$F_{\eta_1}(\omega) = 2\pi A(\omega), \quad (\text{A3})$$

$$F_{\eta_2}(\omega) = 2\pi A(\omega) e^{-ik(\omega)\Delta x}. \quad (\text{A4})$$

464 Then, the power spectra $S_{\eta_1\eta_1}(\omega)$ and $S_{\eta_2\eta_2}(\omega)$ for $\eta_1(t)$ and $\eta_2(t)$, respectively, are shown
 465 as:

$$S_{\eta_1\eta_1}(\omega) = \frac{1}{t_m} F_{\eta_1}^*(\omega) F_{\eta_1}(\omega) = \frac{1}{t_m} 4\pi^2 |A(\omega)|^2, \quad (\text{A5})$$

$$S_{\eta_2\eta_2}(\omega) = \frac{1}{t_m} F_{\eta_2}^*(\omega) F_{\eta_2}(\omega) = S_{\eta_1\eta_1}(\omega). \quad (\text{A6})$$

468 Here, the superscript * indicates the complex conjugate number. The cross-spectrum
 469 $Cr(\omega)$ for $\eta_1(t)$ and $\eta_2(t)$ is shown as:

$$Cr(\omega) = \frac{1}{t_m} F_{\eta_1}^*(\omega) F_{\eta_2}(\omega) = \frac{1}{t_m} 4\pi^2 |A(\omega)|^2 e^{ik(\omega)\Delta x}. \quad (\text{A7})$$

470 Using Euler's theorem, Eq. (A7) transforms to:

$$\begin{aligned} Cr(\omega) &= \frac{1}{t_m} 4\pi^2 |A(\omega)|^2 (\cos k(\omega)\Delta x + i \sin k(\omega)\Delta x) \\ &= S_{\eta_1}(\omega) (\cos k(\omega)\Delta x + i \sin k(\omega)\Delta x). \end{aligned} \quad (\text{A8})$$

474 The cospectrum $Co(\omega)$ and quad spectrum $Q(\omega)$ are defined as the real and imaginary
 475 parts of $Cr(\omega)$, respectively, shown as $Cr(\omega) = Co(\omega) + iQ(\omega)$. Moreover, the phase $\theta(\omega)$
 476 is defined as $\theta(\omega) = \tan^{-1}(Q(\omega)/Co(\omega))$. Thus, $\theta(\omega)$ can be calculated as:

$$\theta(\omega) = \tan^{-1}(\tan(k(\omega)\Delta x) = k(\omega)\Delta x. \quad (\text{A9})$$

478 Generally, the velocity of the wind waves C is defined as:

$$C = \frac{\omega}{k} = \frac{L}{T}, \quad (\text{A10})$$

479 where L is the wavelength and T is the wave period. From Eqs. (A9, A10), $C(\omega)$ and $L(\omega)$

481 can be transformed to

$$C(\omega) = \frac{\omega}{k} = \frac{\omega \Delta x}{\theta(\omega)}, \quad (\text{A11})$$

482

$$L(\omega) = \frac{2\pi}{k} = \frac{2\pi \Delta x}{\theta(\omega)}. \quad (\text{A12})$$

483

484 When we estimate the phase $\theta_m(\omega_m)$ at the angular frequency of significant wind-waves
485 $\omega_m (=2\pi f_m)$, the phase velocity of the significant wind waves $C_S (= C(\omega_m))$ and significant
486 wavelength $L_S (= L(\omega_m))$ are calculated by:

$$C_S = \frac{2\pi f_m \Delta x}{\theta(f_m)}, \quad (\text{A13})$$

487

$$L_S = \frac{2\pi \Delta x}{\theta(f_m)}. \quad (\text{A14})$$

488

489 In the study, C_S and L_S are estimated by Eqs. (A13, A14) using the cross-spectrum
490 method.
